

Sutamaya

Requirements

Concept: Progressive Web App (PWA)

Platform: iOS, iPad, macOS, Web

Storage: Firebase & Persistent local storage

Data

Segmented JSON files (stored on disk) for suttas in English & corresponding Pali

- English and Pali texts are in JSON files in segments where each key represents the segment.
- Dictionary entries are a big JSON array where each object has key `entry` for the word being defined and an array `definitions` containing all definitions for that word (with HTML)

User lists, notes, and highlights stored in Firebase per authenticated user.

User should be able to download then as JSON from the Settings page.

Design

All the UI and data should load at once on the first go, to make everything snappy, fast, and feeling offline.

Sections

- Home
- Sutta Browser
- List Viewer
- Reader (should be immersive with minimal UI like Apple Books)

Home

- Authentication (GAuth)
- 2-3 last visited (see what the visited status means below).
- Settings icon (to set things such as UI font size)
- Search (key "/")
 - By sutta ID, lists, notes, chapters, sutta contents, and TODO: whatever would be useful).

- Filter by searching only certain folders or (all) lists. This should be doable in the inline dropdown that appears when the search is activated.
- When search is activated it should display the history of visited pages inline as long as no text was entered into it.
- When searching, results should appear inline (don't wait for Enter or display another page)

In a big enough resolution, the purpose of a separate home page might not make sense, because the above may be squeezed into the browsing screens.

Reader

Apple Books like experience sutta reader. No pages, just scrolling. Immersive, fills the whole screen. Same UI like Apple Books:

- Close button (to return back to where it was opened from). Keyboard ESC should do the same.
- The following buttons should be collapsed into a hamburger like button on mobile (also like on Apple Books):
 - Highlights & Notes button, displays all highlights in a list and allows jumping to them. (key: H). At the top, it displays the sutta's editable note.
 - Lists: add the sutta to one or more lists (key: L).
 - If available, it should support changing the text data source to view alternative translations.
 - Typography: allows changing font family, size, and line height, as well as switching between dark, light, and sepia.

Reading

- Shows (nikaya, chapter, volume, etc) title, blob, reading time, and body
- It should be possible to go to the next/previous sutta using right/left arrows on the keyboard or swiping on mobile.
- Clicking on a line toggles the display of Pali text. Clicking on a Pali word displays the dictionary entry. On mobile, scrolling should not trigger this, only tapping. Pressing ESC closes the dictionary entry.

Organizing

- Highlighting (in a few standard colors such as pale yellow and two more, or underline in red). It should be possible to select and highlight only the English

text without triggering the Pali display or selecting it. If any Pali is visible, it should be hidden once selection starts.

- Suttas can have **notes**, which are displayed in the browser (and in lists) instead of the blobs.
- Suttas can be added to one or more lists. When doing so, an input box should be focused and allow typing a list name (creating it if inexistent). Submitting adds the sutta to that list and resets the process, allowing more lists to be selected. A simple tree below should show existing lists and allow adding through it alternately (as well as creating a new list)

Visited

Suttas should be marked as "**visited**" according to a criteria (e.g. spent more than 30 seconds on it). This should be reflected when browsing them (as a small discreet checkmark -- should not stand out).

Sutta browser

Browse the EBT.

- Show sutta ID, English title with small Pali title underneath in a slightly more faded but readable color, full blob (or note if it exists) and lists a sutta is in (like the tags in RainDrop).
- Edit sutta note and lists (reveal actions on swiping: delete, edit).

List viewer

Browse your own nested lists.

- Create new lists, move them, nest them.
- Lists should have a default (folder) icon but should allow any emoji to be chosen instead.
- Each sutta should show the note that was added to it, or, the blob if there is no note.
- Arrange suttas in lists manually.
- Edit sutta note and lists (reveal actions on swiping: delete, edit).
